

Chapter 478

Group-Sequential Non-Inferiority Tests for Two Means (Simulation) (Legacy)

This procedure uses simulation for the calculation of the boundaries as well as for calculation of power (and sample size). Futility boundaries are limited. Two test statistics and a variety of simulated distributions are available.

Introduction

This procedure can be used to determine power, sample size and/or boundaries for group sequential non-inferiority tests comparing the means of two groups. The common two-sample T-Test and the Mann-Whitney U test can be simulated in this procedure. Significance and futility boundaries can be produced. The spacing of the looks can be equal or custom specified. Boundaries can be computed based on popular alpha- and beta-spending functions (O'Brien-Fleming, Pocock, Hwang-Shih-DeCanis Gamma family, linear) or custom spending functions. Boundaries can also be input directly to verify alpha- and/or beta-spending properties. Futility boundaries can be binding or non-binding. Maximum and average (expected) sample sizes are reported as well as the alpha and/or beta spent and incremental power at each look. Corresponding P-Value boundaries are also given for each boundary statistic. Plots of boundaries are also produced.

Technical Details

This section outlines many of the technical details of the techniques used in this procedure including the simulation summary, the test statistic details, and the use of spending functions.

An excellent text for the background and details of many group-sequential methods is Jennison and Turnbull (2000).

Simulation Procedure

In this procedure, a large number of simulations are used to calculate boundaries and power using the following steps:

1. Based on the specified distributions, random samples of size N_1 and N_2 are generated under the null distribution and under the alternative distribution. These are simulated samples as though the final look is reached.
2. For each sample, test statistics for each look are produced. For example, if N_1 and N_2 are 100 and there are 5 equally spaced looks, test statistics are generated from the random samples at $N_1 = N_2 = 20$, $N_1 = N_2 = 40$, $N_1 = N_2 = 60$, $N_1 = N_2 = 80$, and $N_1 = N_2 = 100$ for both null and alternative samples.

Group-Sequential Non-Inferiority Tests for Two Means (Simulation) (Legacy)

3. To generate the first significance boundary, the null distribution statistics of the first look (e.g., at $N_1 = N_2 = 20$) are ordered and the percent of alpha to be spent at the first look is determined (using either the alpha-spending function or the input value). The statistic for which the percent of statistics above (or below, as the case may be) that value is equal to the percent of alpha to be spent at the first look is the boundary statistic. It is seen here how important a large number of simulations is to the precision of the boundary estimates.
4. All null distribution samples that are outside the first significance boundary at the first look are removed from consideration for the second look. If binding futility boundaries are also being computed, all null distribution samples with statistics that are outside the first futility boundary are also removed from consideration for the second look. If non-binding futility boundaries are being computed, null distribution samples with statistics outside the first futility boundary are not removed.
5. To generate the second significance boundary, the remaining null distribution statistics of the second look (e.g., at $N_1 = N_2 = 40$) are ordered and the percent of alpha to be spent at the second look is determined (again, using either the alpha-spending function or the input value). The percent of alpha to be spent at the second look is multiplied by the total number of simulations to determine the number of the statistic that is to be the second boundary statistic. The statistic for which that number of statistics is above it (or below, as the case may be) is the second boundary statistic. For example, suppose there are initially 1000 simulated samples, with 10 removed at the first look (from, say, alpha spent at Look 1 equal to 0.01), leaving 990 samples considered for the second look. Suppose further that the alpha to be spent at the second look is 0.02. This is multiplied by 1000 to give 20. The 990 still-considered statistics are ordered and the 970th (20 in from 990) statistic is the second boundary.
6. All null distribution samples that are outside the second significance boundary and the second futility boundary, if binding, at the second look are removed from consideration for the third look (e.g., leaving 970 statistics computed at $N_1 = N_2 = 60$ to be considered at the third look). Steps 4 and 5 are repeated until the final look is reached.

Futility boundaries are computed in a similar manner using the desired beta-spending function or custom beta-spending values and the alternative hypothesis simulated statistics at each look. For both binding and non-binding futility boundaries, samples for which alternative hypothesis statistics are outside either the significance or futility boundaries of the previous look are excluded from current and future looks.

Because the final futility and significance boundaries are required to be the same, futility boundaries are computed beginning at a small value of beta (e.g., 0.0001) and incrementing beta by that amount until the futility and significance boundaries meet.

When boundaries are entered directly, this procedure uses the null hypothesis and alternative hypothesis simulations to determine the number of test statistics that are outside the boundaries at each look. The cumulative proportion of alternative hypothesis statistics that are outside the significance boundaries is the overall power of the study.

Generating Random Distributions

Two methods are available in **PASS** to simulate random samples. The first method generates the random variates directly, one value at a time. The second method generates a large pool (over 10,000) of random values and then draws the random numbers from this pool. This second method can cut the running time of the simulation by 70%.

As mentioned above, the second method begins by generating a large pool of random numbers from the specified distributions. Each of these pools is evaluated to determine if its mean is within a small relative tolerance (0.0001) of the target mean. If the actual mean is not within the tolerance of the target mean, individual members of the population are replaced with new random numbers if the new random number moves the mean towards its target. Only a few hundred such swaps are required to bring the actual mean to within tolerance of the target mean. This population is then sampled with replacement using the uniform distribution. We have found that this method works well as long as the size of the pool is the maximum of twice the number of simulated samples desired and 10,000.

The Statistical Hypotheses

This section will review the specifics of non-inferiority testing.

Remember that in the usual t-test setting, the null (H_0) and alternative (H_1) hypotheses for one-sided tests are defined as

$$H_0: \mu_1 - \mu_2 \leq D \quad \text{versus} \quad H_1: \mu_1 - \mu_2 > D$$

Rejecting this test implies that the mean difference is larger than the value D . This test is called an *upper-tailed test* because it is rejected in samples in which the difference between the sample means is larger than D .

Following is an example of a *lower-tailed test*.

$$H_0: \mu_1 - \mu_2 \geq D \quad \text{versus} \quad H_1: \mu_1 - \mu_2 < D$$

Non-inferiority tests are special cases of the above directional tests. It will be convenient to adopt the following specialized notation for the discussion of these tests.

Group-Sequential Non-Inferiority Tests for Two Means (Simulation) (Legacy)

| Parameter | PASS Input/Output | Interpretation |
|------------------|--------------------------|--|
| μ_1 | Mean1 | <i>Mean</i> of population 1. Population 1 is assumed to consist of those who have received the new treatment. |
| μ_2 | Mean2 | <i>Mean</i> of population 2. Population 2 is assumed to consist of those who have received the reference treatment. |
| M_{NI} | NIM | <i>Margin of non-inferiority</i> . This is a tolerance value that defines the magnitude of the amount that is not of practical importance. This may be thought of as the largest change from the baseline that is considered to be trivial. The absolute value is shown to emphasize that this is a magnitude. The sign of the value will be determined by the specific design that is being used. |
| δ | D | <i>True difference</i> . This is the value of $\mu_1 - \mu_2$, the difference between the means. This is the value at which the power is calculated. |

Note that the actual values of μ_1 and μ_2 are not needed. Only their difference is needed for power and sample size calculations.

Non-Inferiority Tests

A *non-inferiority test* tests that the treatment mean is not worse than the reference mean by more than the equivalence margin. The actual direction of the hypothesis depends on the response variable being studied.

Case 1: High Values Good, Non-Inferiority Test

In this case, higher values are better. The hypotheses are arranged so that rejecting the null hypothesis implies that the treatment mean is no less than a small amount below the reference mean. The value of δ is often set to zero. The following are equivalent sets of hypotheses.

$$\begin{array}{lll}
 H_0: \mu_1 \geq \mu_2 + |M_{NI}| & \text{versus} & H_1: \mu_1 < \mu_2 + |M_{NI}| \\
 H_0: \mu_1 - \mu_2 \geq |M_{NI}| & \text{versus} & H_1: \mu_1 - \mu_2 < |M_{NI}| \\
 H_0: \delta \geq |M_{NI}| & \text{versus} & H_1: \delta < |M_{NI}|
 \end{array}$$

Case 2: High Values Bad, Non-Inferiority Test

In this case, lower values are better. The hypotheses are arranged so that rejecting the null hypothesis implies that the treatment mean is no more than a small amount above the reference mean. The value of δ is often set to zero. The following are equivalent sets of hypotheses.

$$\begin{array}{lll}
 H_0: \mu_1 \leq \mu_2 - |M_{NI}| & \text{versus} & H_1: \mu_1 > \mu_2 - |M_{NI}| \\
 H_0: \mu_1 - \mu_2 \leq -|M_{NI}| & \text{versus} & H_1: \mu_1 - \mu_2 > -|M_{NI}| \\
 H_0: \delta \leq -|M_{NI}| & \text{versus} & H_1: \delta > -|M_{NI}|
 \end{array}$$

Test Statistics

This section describes the test statistics that are available in this procedure.

Two-Sample T-Test

The two-sample t-test assumes that the data are a simple random sample from a population of normally distributed values that all have the same mean and variance. This assumption implies that the data are continuous, and their distribution is symmetric. The calculation of the t statistic is as follows

$$t_{df} = \frac{(\bar{X}_1 - \bar{X}_2) - (\mu_1 - \mu_2)}{s_{\bar{X}_1 - \bar{X}_2}}$$

where

$$\bar{X}_k = \frac{\sum_{i=1}^{N_k} X_{ki}}{N_k}$$

$$s_{\bar{X}_1 - \bar{X}_2} = \sqrt{\frac{\sum_{i=1}^{N_1} (X_{1i} - \bar{X}_1)^2 + \sum_{i=1}^{N_2} (X_{2i} - \bar{X}_2)^2}{N_1 + N_2 - 2} \left(\frac{1}{N_1} + \frac{1}{N_2} \right)}$$

$$df = N_1 + N_2 - 2$$

The significance of the test statistic is determined by computing the p-value based on the t distribution with degrees of freedom df . If this p-value is less than a specified level (often 0.05), the null hypothesis is rejected. Otherwise, no conclusion can be reached.

Mann-Whitney U Test

This test is the nonparametric substitute for the equal-variance t-test. Two key assumptions for this test are that the distributions are at least ordinal and that they are identical under H_0 . This implies that ties (repeated values) are not acceptable. When ties are present, the approximation provided can be used, but know that the theoretic results no longer hold.

The Mann-Whitney test statistic is defined as follows in Gibbons (1985).

$$z = \frac{W_1 - \frac{N_1(N_1 + N_2 + 1)}{2} + C}{s_W}$$

where

$$W_1 = \sum_{k=1}^{N_1} \text{Rank}(X_{1k})$$

Group-Sequential Non-Inferiority Tests for Two Means (Simulation) (Legacy)

The ranks are determined after combining the two samples. The standard deviation is calculated as

$$s_W = \sqrt{\frac{N_1 N_2 (N_1 + N_2 + 1)}{12} - \frac{N_1 N_2 \sum_{i=1}^n (t_i^3 - t_i)}{12(N_1 + N_2)(N_1 + N_2 - 1)}}$$

where t_1 is the number of observations tied at value one, t_2 is the number of observations tied at some value two, and so forth.

The correction factor, C , is 0.5 if the rest of the numerator of z is negative or -0.5 otherwise. The value of z is then compared to the standard normal distribution.

Spending Functions

Spending functions can be used in this procedure to specify the proportion of alpha or beta that is spent at each look without having to specify the proportion directly.

Spending functions have the characteristics that they are increasing and that

$$\alpha(0) = 0$$

$$\alpha(1) = \alpha$$

The last characteristic guarantees a fixed α level when the trial is complete. This methodology is very flexible since neither the times nor the number of analyses must be specified in advance. Only the functional form of $\alpha(\tau)$ must be specified.

PASS provides several popular spending functions plus the ability to enter and analyze your own percents of alpha or beta spent. These are calculated as follows (beta may be substituted for alpha for beta-spending functions):

1. **Hwang-Shih-DeCani (gamma family)** $\alpha \left[\frac{1-e^{-\gamma t}}{1-e^{-\gamma}} \right], \gamma \neq 0; \quad \alpha t, \gamma = 0$

Group-Sequential Non-Inferiority Tests for Two Means (Simulation) (Legacy)

2. O'Brien-Fleming Analog $2 - 2\Phi\left(\frac{Z_{\alpha/2}}{\sqrt{t}}\right)$ 3. Pocock Analog $\alpha \cdot \ln(1 + (e - 1)t)$ 4. Alpha * time $\alpha \cdot t$ 

Group-Sequential Non-Inferiority Tests for Two Means (Simulation) (Legacy)

5. $\text{Alpha} \cdot \text{time}^{1.5} \quad \alpha \cdot t^{3/2}$ 6. $\text{Alpha} \cdot \text{time}^2 \quad \alpha \cdot t^2$ 7. $\text{Alpha} \cdot \text{time}^C \quad \alpha \cdot t^C$ 

8. User Supplied Percents

A custom set of percents of alpha to be spent at each look may be input directly.

The O'Brien-Fleming Analog spends very little alpha or beta at the beginning and much more at the final looks. The Pocock Analog and (Alpha or Beta)(Time) spending functions spend alpha or beta more evenly across the looks. The Hwang-Shih-DeCani (C) (gamma family) spending functions and (Alpha or Beta)(Time^C) spending functions are flexible spending functions that can be used to spend more alpha or beta early or late or evenly, depending on the choice of C.

Example 1 – Power and Output

A clinical trial is to be conducted over a two-year period to compare the mean response of a new treatment to that of the current treatment. The current response mean is 108. The researchers would like to determine if the new treatment is not inferior to the current treatment, as it has fewer side effects and is less expensive. The new treatment is considered non-inferior if it has a mean greater than 103. Although the researchers do not know the true mean of the new treatment, they would like to examine the power that is achieved if the mean of the new treatment is also 108. The standard deviation for both groups is assumed to be 20. The sample size at the final look is to be 200 per group. Testing will be done at the 0.05 significance level. A total of five tests are going to be performed on the data as they are obtained. The O'Brien-Fleming (Analog) boundaries will be used

Find the power and test boundaries assuming equal sample sizes per arm.

Setup

If the procedure window is not already open, use the PASS Home window to open it. The parameters for this example are listed below and are stored in the **Example 1** settings file. To load these settings to the procedure window, click **Open Example Settings File** in the Help Center or File menu.

Power The probability of rejecting a false null hypothesis at one of the looks. It is the total proportion of alternative hypothesis simulations that are outside the significance boundaries.

Power 95% LCL and UCL The lower and upper confidence limits for the power estimate. The width of the interval is based on the number of simulations.

Target Alpha The user-specified probability of rejecting a true null hypothesis. It is the total alpha spent.

Actual Alpha The alpha level that was actually achieved by the experiment. It is the total proportion of the null hypothesis simulations that are outside the significance boundaries.

Alpha 95% LCL and UCL The lower and upper confidence limits for the actual alpha estimate. The width of the interval is based on the number of simulations.

Beta The probability of accepting a false null hypothesis. It is the total proportion of alternative hypothesis simulations that do not cross the significance boundaries.

N1 and N2 The sample sizes of each group if the study reaches the final look.

Average Sample Size Given H0 The average or expected sample sizes of each group if H0 is true. These are based on the proportion of null hypothesis simulations that cross the significance or futility boundaries at each look.

Average Sample Size Given H1 The average or expected sample sizes of each group if H1 is true. These are based on the proportion of alternative hypothesis simulations that cross the significance or futility boundaries at each look.

Non-Inferiority Margin The distance from the control mean that is still considered non-inferior.

Mean1, Mean2, and Std Dev The parameters that were set by the user to define the null and alternative simulation distributions.

Group-Sequential Non-Inferiority Tests for Two Means (Simulation) (Legacy)

Summary Statements

A group sequential trial with group sample sizes of 200 and 200 at the final look achieves 80% power to detect a difference of 5 at the 0.05 significance level (alpha) using a one-sided T-Test.

Accumulated Information Details for Scenario 1

| Look | Accumulated Information Percent | Accumulated Sample Size | | |
|------|---------------------------------------|-------------------------|---------|-------|
| | | Group 1 | Group 2 | Total |
| 1 | 20 | 40 | 40 | 80 |
| 2 | 40 | 80 | 80 | 160 |
| 3 | 60 | 120 | 120 | 240 |
| 4 | 80 | 160 | 160 | 320 |
| 5 | 100 | 200 | 200 | 400 |

Look
 Accumulated Information Percent
 Accumulated Sample Size Group 1
 Accumulated Sample Size Group 2
 Accumulated Sample Size Total

The number of the look.
 The percent of the sample size accumulated up to the corresponding look.
 The total number of individuals in group 1 at the corresponding look.
 The total number of individuals in group 2 at the corresponding look.
 The total number of individuals in the study (group 1 + group 2) at the corresponding look.

Boundaries for Scenario 1

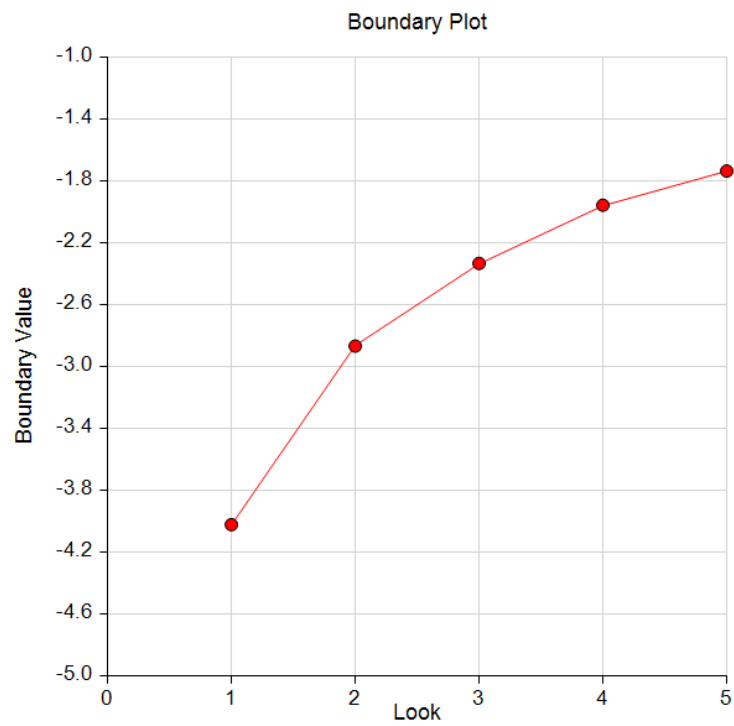

| Look | Significance Boundary | |
|------|-----------------------|------------------|
| | T-Value Scale | P-Value Scale |
| 1 | -4.02184 | 0.00007 |
| 2 | -2.86704 | 0.00235 |

| Alpha or Actual Alpha | The alpha level that was actually achieved by the experiment. It is the total proportion of the null hypothesis simulations that are outside the significance boundaries. |
| Alpha 95% LCL and UCL | The lower and upper confidence limits for the actual alpha estimate. The width of the interval is based on the number of simulations. |
| Beta | The probability of accepting a false null hypothesis. It is the total proportion of alternative hypothesis simulations that do not cross the significance boundaries. |

Group-Sequential Non-Inferiority Tests for Two Means (Simulation) (Legacy)

Sample Size Summary

| Scenario | Power | Alpha | N1 | N2 | Average Sample Size | | | |
|----------|--------|-------|-----|-----|---------------------|------|----------|------|
| | | | | | Given H0 | | Given H1 | |
| | | | | | Grp1 | Grp2 | Grp1 | Grp2 |
| 1 | 0.7982 | 0.05 | 200 | 200 | 198 | 198 | 156 | 156 |

| | | | | | | | | |
|------------------------------|--|--|--|--|--|--|--|--|
| Power | The probability of rejecting a false null hypothesis at one of the looks. It is the total proportion of alternative hypothesis simulations that are outside the significance boundaries. | | | | | | | |
| Alpha | The alpha level that was actually achieved by the experiment. It is the total proportion of the null hypothesis simulations that are outside the significance boundaries. | | | | | | | |
| N1 and N2 | The sample sizes of each group if the study reaches the final look. | | | | | | | |
| Average Sample Size Given H0 | The average or expected sample sizes of each group if H0 is true. These are based on the proportion of null hypothesis simulations that cross the significance or futility boundaries at each look. | | | | | | | |
| Average Sample Size Given H1 | The average or expected sample sizes of each group if H1 is true. These are based on the proportion of alternative hypothesis simulations that cross the significance or futility boundaries at each look. | | | | | | | |

Run Time: 12.19 seconds.

The values obtained from any given run of this example will vary slightly due to the variation in simulations.

Example 2 – Power for One-Sided Test with Futility Boundaries

Suppose researchers would like to compare two treatments with a non-inferiority test at each look. Further, suppose they would like to terminate the study early when it can be deemed highly unlikely that the new treatment is non-inferior to the standard. Suppose the control group mean is 108. The researchers wish to know the power of the test if the treatment group mean is also 108. The sample size at the final look is to be 200 per group. Testing will be done at the 0.05 significance level. A total of five tests are going to be performed on the data as they are obtained. The O'Brien-Fleming (Analog) boundaries will be used for both significance and futility boundaries.

Find the power and test boundaries assuming equal sample sizes per arm.

Setup

If the procedure window is not already open, use the PASS Home window to open it. The parameters for this example are listed below and are stored in the **Example 2** settings file. To load these settings to the procedure window, click **Open Example Settings File** in the Help Center or File menu.
