Chapter 361

Mixed Models Tests for Slope-Interaction in a 2×2 Factorial 2-Level Hierarchical Design with Random Slopes (Level-2 Randomization)

Introduction

This procedure calculates power and sample size for a two-level hierarchical mixed model which is randomized at the **second** level (subjects). The associated **longitudinal** study uses a 2-by-2 factorial design with two binary factors X and Z, each with two possible values (0 and 1). This results in four treatment arms. The goal of the study is to test whether the slopes of subjects across time are different from what would be expected if the effect of the two factors were additive. That is, one wants to test the three-way interaction between the two binary factors and time.

In many cases, this design is called a *repeated measures* design. The classic example is a study in which the level-2 units are subjects, and the level-1 units are time points at which measurements are taken. This factor is nested in the level-2 units.

This procedure is for longitudinal studies in which each subject is measured two or more times.

In this case of level-2 randomization, each level-2 unit (subject) is randomly assigned to one of the four treatments combinations.

Each subject is assumed to have a separate, random slope.

Technical Details

Our formulation comes from Ahn, Heo, and Zhang (2015), chapter 5, section 5.6, pages 172-176. The linear mixed model that is adopted is

$$Y_{ij} = \beta_0 + \delta_X X_{ij} + \delta_Z Z_{ij} + \delta_T T_{ij} + \delta_{XZ} X_{ij} Z_{ij} + \delta_{XT} X_{ij} T_{ij} + \delta_{ZT} Z_{ij} T_{ij} + \boldsymbol{\delta_{XZT}} \boldsymbol{X_{ij}} \boldsymbol{Z_{ij}} \boldsymbol{T_{ij}} + \boldsymbol{v_i} T_{ij} + \boldsymbol{u_i} + \boldsymbol{e_{ij}}$$

where

- Y_{ij} is the continuous response of the j^{th} level-1 unit, within the i^{th} level-2 unit.
- X_{ij} is an indicator variable that is equal to "1" if the i^{th} level-2 unit is assigned to receive intervention X and "0" otherwise. Thus, $X_{ij} = Xi$ for all i.
- Z_{ij} is an indicator variable that is equal to "1" if the i^{th} level-2 unit is assigned to receive intervention Z and "0" otherwise. Thus, $Z_{ij} = Zi$ for all i.
- β_0 is the fixed intercept.

Mixed Models Tests for Slope-Interaction in a 2×2 Factorial 2-Level Hier. Design with Random Slopes (Level-2 Rand.)

 δ_X is the treatment effect of factor X.

 $\delta_{\rm Z}$ is the treatment effect of factor Z.

 δ_{XZ} is the interaction effect of factors X and Z.

 δ_{XT} is the interaction effect of factors X and Z.

 δ_{ZT} is the interaction effect of factors X and Z.

 δ_{XZT} is the 3-way interaction effect of X, Z, and time. **This is the coefficient of interest**.

 v_i is the random slope of the i^{th} level-2 unit. It is distributed as $N(0, \sigma_{\tau}^2)$.

 u_i is the random intercept for the i^{th} level-2 unit. It is distributed as $N(0, \sigma_2^2)$.

 e_{ij} is the level-1 random intercept effect that is distributed as $N(0, \sigma_e^2)$.

 σ_{τ}^2 is variance of the subject-specific random slopes.

 σ^2 is the variance of Y when slopes are fixed, where $\sigma^2 = \sigma_2^2 + \sigma_e^2$.

 ρ_1 is the correlation among level-1 units which are in a particular level-2 unit.

 $r_{ au}$ is the ratio of the random-slope variance to the sum of the other variances. So $r_{ au} = \frac{\sigma_{ au}^2}{\sigma^2}$

 $K_{0,0}$ is the number of level-2 units for which X = 0 and Z = 0.

 $K_{0.1}$ is the number of level-2 units for which X = 0 and Z = 1.

 $K_{1,0}$ is the number of level-2 units for which X = 1 and Z = 0.

 $K_{1,1}$ is the number of level-2 units for which X = 1 and Z = 1.

M is the number of level-1 units per level-2 unit. It is the number of measurement times.

The test of significance of the product $X_{ijk}Z_{ijk}T_{ijk}$ is the interaction effect of X, Z, and Time. This is the test statistic of interest. It tests whether the subject-specific slopes behave the same across all treatment combinations.

Assume that δ_{XZT} is to be tested using a Wald test. The statistical hypotheses are H_0 : $\delta_{XZT} = 0$ vs. H_a : $\delta_{XZT} \neq 0$.

The power is calculated using

$$Power = \Phi \left\{ \left| \frac{\delta_{XZT}}{\sigma} \right| \sqrt{\frac{K_{0,0}M \operatorname{Var}(T)}{f\left(\frac{1}{K_{0,0}} + \frac{1}{K_{1,1}} + \frac{1}{K_{1,0}} + \frac{1}{K_{0,1}}\right)} - \Phi^{-1}(1 - \alpha/2) \right\}$$

Mixed Models Tests for Slope-Interaction in a 2×2 Factorial 2-Level Hier. Design with Random Slopes (Level-2 Rand.)

Example 1 – Calculating Power

Suppose that a two-level hierarchical design is planned in which there will be two interventions. Each intervention will be whether one of two drugs is administered. There will be only one measurement per subject and the four treatments will be applied to whole clusters (level-two units). The analysis will be a mixed model of continuous data using the model given earlier in this chapter. The following parameter settings are to be used for the power analysis: $\delta xz\tau = 7$; $\sigma = 9.7$; $\rho = 0.06$; $\tau = 0.1$; and $\tau = 0.1$; $\tau = 0.1$; and $\tau = 0.1$; $\tau = 0.1$; and $\tau = 0.1$; $\tau = 0.1$; $\tau = 0.1$; $\tau = 0.1$; and $\tau = 0.1$; and $\tau = 0.1$; $\tau = 0.1$; and $\tau = 0.1$; and

Setup

If the procedure window is not already open, use the PASS Home window to open it. The parameters for this example are listed below and are stored in the **Example 1** settings file. To load these settings to the procedure window, click **Open Example Settings File** in the Help Center or File menu.

Alpha

A 2×2 factorial (X = 0,1 and Z = 0,1) 2-level design will have random assignment of subjects (level-2 units) to each of the 4 treatment arms (Groups 00, 01, 10, and 11), with repeated measurements (level-1 units) on each subject (over time). This design will be used to test whether the outcome trends (slopes) are different for each of the treatment combinations (or, equivalently, whether the group combination mean differences change across time). This hypothesis will be evaluated by testing the three-way interaction term (X x Z x time) of the linear mixed-effects model, assuming random slopes, with a Type I error rate (α) of 0.05. This interaction is formed from the four group slopes across time using the following formula: $\delta xz\tau = (\beta 11 - \beta 10) - (\beta 01 - \beta 00)$. The standard deviation of Yij, assuming a fixed-slope model, is assumed to be 9.7 (this standard deviation is the square-root of the fixed-slope model variance of Yij (σ^2), where the variance is the sum of the error term variance and the level-2 random intercept variance). The ratio of the subject-specific random slope variance to σ^2 (V(τ) / σ^2) is assumed to be 0.1 (the variance of Yij, assuming a random-slope model, is $\sigma^2 + V(\tau) \times T[k]^2$). The intraclass correlation coefficient of level-1 units (repeated measurements on a subject) is assumed to be 0.06. To detect a three-way interaction among the subject-specific slopes (δxzt) of at least 7, with level-2 (subject-level) sample sizes of 5 in Group 00 (X = 0, Z = 0), 5 in Group 01 (X = 0, Z = 1), 5 in Group 10 (X = 1, Z = 0), and 5 in Group 11 (X = 1, Z = 1), with 5 level-1 units (repeated measurements) obtained from each level-2 unit (subject) (for a grand total of 100 level-1 measurements), the power is 0.449.

Example 2 - Calculating Sample Size (K00)

Continuing with the last example, suppose the researchers want to determine the value of K00 needed to achieve 90% power for both values of M.

Setup

If the procedure window is not already open, use the PASS Home window to open it. The parameters for this example are listed below and are stored in the **Example 2** settings file. To load these settings to the procedure window, click **Open Example Settings File** in the Help Center or File menu.
