#### Chapter 348

# Multi-Arm Superiority by a Margin Tests for Vaccine Efficacy using the Ratio of Treatment and Control Proportions

#### Introduction

This module computes power and sample size for multi-arm, superiority by a margin tests for vaccine efficacy (VE) using the ratio of treatment and control proportions. VE is a traditional index of the protective efficacy of a vaccine. It is calculated as

$$VE_i = \frac{P_C - P_i}{P_C} = 1 - \frac{P_i}{P_C}$$

where  $P_i$  and  $P_C$  are attack rates of the disease being studied among those vaccinated and those not vaccinated. An attack rate is the probability that a subject without the disease at the beginning of the study is infected by it during the duration of the study. Hence, an analysis of vaccine effectiveness reduces to an analysis of the ratio of two proportions.

The multi-arm nature of this procedure is based on the results in Machin, Campbell, Tan, and Tan (2018). In this design, there are k treatment groups and one control group. The groups are independent and are sampled using simple random sampling. A proportion (event probability) is measured for each group. A total of k hypothesis tests are anticipated, each comparing a treatment group with the common control group using a superiority by a margin test based on the ratio of two proportions.

The Bonferroni multiplicity adjustment of the type I error rate may be optionally made because several tests are being constructed from the same data. Making a multiplicity adjustment is usually recommended, but not always. In fact, Saville (1990) advocates not applying it and Machin, Campbell, Tan, and Tan (2018) include omitting it as a possibility.

Whether you want to test several doses of a single treatment or several types of treatments, good research practice requires that each treatment be compared with a control. For example, a popular three-arm design consists of three groups: control, treatment A, and treatment B. Two tests are run: treatment A versus control and treatment B versus the same control. This avoids having to obtain a second control group for treatment B. Besides the obvious efficiency in subjects, it may be easier to recruit subjects if their chances of receiving a new treatment are better than 50%.

Multi-Arm Superiority by a Margin Tests for Vaccine Efficacy using the Ratio of Treatment and Control Proportions

# **Relative Vaccine Efficacy**

Often, the goal of the study is to show that the attack rate of a new vaccine is more favorable than that of the current standard vaccine. For example, the standard vaccine might have serious side effects, be expensive to produce, etc. In this case, the trial is conducted to show that the new vaccine is an attractive replacement for the standard vaccine. In this case, the control group does not receive a placebo. Rather, it receives the standard vaccine. In this case, the quantity of interest is called the *relative vaccine efficacy (rVE)*. It is calculated as

$$rVE_i = \frac{P_C - P_i}{P_C} = 1 - \frac{P_i}{P_C}$$

where now  $P_C$  is the attack rate for those receiving the standard vaccine.

# **Technical Details**

Suppose you have k treatment groups with event probabilities  $P_i$  of size  $N_i$  and one control group with event probability  $P_C$  of size  $N_C$ . The total sample size is  $N = N_1 + N_2 + ... + N_k + N_C$ .

If we define  $VE_0$  to be the superiority bound on vaccine efficacy, the k one-sided superiority by a margin tests are

$$H_{0i}: VE_i \leq VE_0$$
 vs.  $H_{1i}: VE_i > VE_0$  for  $i = 1, 2, ..., k$ 

Note that if lower proportions are better, as is usually the case when the studying disease prevention,  $VE_0 < 1$ .

For convenience, these hypotheses are collectively referred to as

$$H_0: VE \leq VE_0$$
 vs.  $H_1: VE > VE_0$ 

These hypotheses may be restated in terms of proportions as

$$H_0: P_i \ge P_0$$
 vs.  $H_1: P_i < P_0$ 

where  $P_0$  is the superiority event probability.

# Transforming from VE to P

It is often useful to transform a  $VE_i$  value into the corresponding  $P_i$ . The transformation formula is

$$P_i = P_C(1 - VE_i)$$

Multi-Arm Superiority by a Margin Tests for Vaccine Efficacy using the Ratio of Treatment and Control Proportions

#### **Test Statistics**

Three common likelihood-score tests are available in this procedure.

#### Miettinen and Nurminen's Likelihood Score Test

Miettinen and Nurminen (1985) proposed a test statistic for testing whether the ratio is equal to a specified value  $R_0$ . The regular MLE's,  $\hat{p}_i$  and  $\hat{p}_C$ , are used in the numerator of the score statistic while MLE's  $\tilde{p}_i$  and  $\tilde{p}_C$ , constrained so that  $\tilde{p}_i$  /  $\tilde{p}_C = R_0$ , are used in the denominator. A correction factor of N/(N-1) is applied to make the variance estimate less biased. The significance level of the test statistic is based on the asymptotic normality of the score statistic.

The formula for computing the test statistic is

$$z_{MNR} = \frac{\hat{p}_i / \hat{p}_C - R_0}{\sqrt{\left(\frac{\tilde{p}_i \tilde{q}_i}{N_i} + R_0^2 \frac{\tilde{p}_C \tilde{q}_C}{N_C}\right) \left(\frac{N}{N-1}\right)}}$$

where

$$\tilde{p}_i = \tilde{p}_C R_0$$

$$\tilde{p}_c = \frac{-B - \sqrt{B^2 - 4AC}}{2A}$$

$$A = NR_0$$

$$B = -[N_i R_0 + x_{11} + N_C + x_{21} R_0]$$

$$C=m_1$$

 $m_1$  = number of successes

#### Farrington and Manning's Likelihood Score Test

Farrington and Manning (1990) proposed a test statistic for testing whether the ratio is equal to a specified value  $R_0$ . The regular MLE's,  $\hat{p}_i$  and  $\hat{p}_C$ , are used in the numerator of the score statistic while MLE's  $\tilde{p}_i$  and  $\tilde{p}_C$ , constrained so that  $\tilde{p}_i$  /  $\tilde{p}_C = R_0$ , are used in the denominator. The significance level of the test statistic is based on the asymptotic normality of the score statistic.

The formula for computing the test statistic is

$$z_{FMR} = \frac{\hat{p}_i / \hat{p}_C - R_0}{\sqrt{\left(\frac{\tilde{p}_i \tilde{q}_i}{N_i} + R_0^2 \frac{\tilde{p}_C \tilde{q}_C}{N_C}\right)}}$$

where the estimates  $\tilde{p}_i$  and  $\tilde{p}_C$  are computed as in the corresponding test of Miettinen and Nurminen (1985) given above.

Multi-Arm Superiority by a Margin Tests for Vaccine Efficacy using the Ratio of Treatment and Control Proportions

#### Gart and Nam's Likelihood Score Test

Gart and Nam (1988), page 329, proposed a modification to the Farrington and Manning (1988) ratio test that corrects for skewness. Let  $z_{FMR}(R)$  stand for the Farrington and Manning ratio test statistic described above. The skewness corrected test statistic,  $z_{GNR}$ , is the appropriate solution to the quadratic equation

$$(-\tilde{\varphi})z_{GNR}^2 + (-1)z_{GNR} + (z_{FMR}(R) + \tilde{\varphi}) = 0$$

where

$$\tilde{\varphi} = \frac{1}{6\tilde{u}^{3/2}} \left( \frac{\tilde{q}_i(\tilde{q}_i - \tilde{p}_i)}{N_i^2 \tilde{p}_i^2} - \frac{\tilde{q}_C(\tilde{q}_C - \tilde{p}_C)}{N_C^2 \tilde{p}_C^2} \right)$$

$$\tilde{u} = \frac{\tilde{q}_i}{N_i \tilde{p}_i} + \frac{\tilde{q}_C}{N_C \tilde{p}_C}$$

# Adapting the Ratio of Two Proportions to Vaccine Efficacy Studies

A traditional index of the protective efficacy of a vaccine is called the vaccine efficacy (VE). It is calculated as

$$VE = \frac{p_C - p_i}{p_C} = 1 - \frac{p_i}{p_C}$$

Note that VE is a simple transformation of the ratio made by subtracting it from one. Thus, methods for the ratio of two proportions can be easily adapted for vaccine efficacy studies. Blackwelder (1993) gives the details. He recommends using the score test of Gart and Nam.

#### **Superiority Bound**

The idea of a superiority by a margin test is that a new treatment is better than the treatment it is being compared to. To allow the comparison to be made, you must determine a superiority boundary. In this procedure, that means that  $p_i$  can must be slightly smaller than  $p_c$ .

Hence, one task that will have to be completed is to determine how much better the new vaccine must be.

# **Asymptotic Approximation to Power**

A large sample approximation is used to compute power. The large sample approximation is made by replacing the values of  $\hat{p}_i$  and  $\hat{p}_c$  in the z statistic with the corresponding values of  $P_i$  and  $P_c$ , and then computing the results based on the normal distribution. Note that in large samples, the Farrington and Manning statistic is substituted for the Gart and Nam statistic.

Multi-Arm Superiority by a Margin Tests for Vaccine Efficacy using the Ratio of Treatment and Control Proportions

# A Note on Setting the Significance Level, Alpha

Setting the significance level has always been somewhat arbitrary. For planning purposes, the standard has become to set alpha to 0.05 for two-sided tests. Almost universally, when someone states that a result is statistically significant, they mean statistically significant at the 0.05 level.

Although 0.05 may be the standard for two-sided tests, it is not always the standard for one-sided tests, such as superiority by a margin tests. Statisticians often recommend that the alpha level for one-sided tests be set at 0.025 since this is the amount put in each tail of a two-sided test.

#### **Multiplicity Adjustment**

Because *k* z-tests between treatment groups and the control group are run when analyzing the results of this study, many statisticians recommend that the Bonferroni adjustment be applied. This adjustment is easy to apply: the value of alpha that is used in the test is found by dividing the original alpha by the number of tests. For example, if the original alpha is set at 0.05 and the number of treatment (not including the control) groups is five, the individual tests will be conducted using an alpha of 0.01.

The main criticism of this procedure is that if there are many tests, the value of alpha becomes very small. To mitigate against this complaint, some statisticians recommend separating the treatment groups into those that are of primary interest and those that are of secondary interest. The Bonferroni adjustment is made by the using the number of primary treatments rather than the total number of treatments.

There are some who advocate ignoring the adjustment entirely in the case of randomized clinical trials. See for example Saville (1990) and the discussion in chapter 14 of Machin, Campbell, Tan, and Tan (2018).

# Size of the Control Group

Because the control group is used over and over, some advocate increasing the number of subjects in this group. The standard adjustment is to include  $\sqrt{k}$  subjects in the control group for each subject in one of the treatment groups. See Machin, Campbell, Tan, and Tan (2018, pages 231-232). Note that often, the treatment groups all have the same size.

# Example 1 - Finding the Sample Size

A parallel-group, clinical trial is being designed to test the superiority by a margin of three dose levels of a test compound against the standard therapy using three superiority by a margin Gart and Nam Likelihood Scores tests. Suppose the standard therapy has an event probability of 0.5. The investigators would like a sample size large enough to detect statistical significance at an overall 0.025 level and an individual-test power of 0.80 when the event rates of treatment group 1 are 0.35, 0.38, 0.40. The event rate of group 2 is 0.35. The event rate of group 3 is 0.36. The superiority ratio is 0.45. This corresponds to a VEO of 0.1.

Following common practice, the control-group sample-size multiplier will be set to  $\sqrt{k} = \sqrt{3} = 1.732$  since there are three treatment groups in this design.

#### Setup

If the procedure window is not already open, use the PASS Home window to open it. The parameters for this example are listed below and are stored in the **Example 1** settings file. To load these settings to the procedure window, click **Open Example Settings File** in the Help Center or File menu.

Multi-Arm Superiority by a Margin Tests for Vaccine Efficacy using the Ratio of Treatment and Control Proportions

#### **Summary Statements**

A parallel, 4-group design (with one control group and 3 treatment groups) will be used to test whether the event probability for each treatment group (Pi) is superior to the control group event probability (Pc) by a margin, with a superiority event probability limit of 0.45 (H0: Pi  $\geq$  0.45 versus H1: Pi < 0.45, or the corresponding hypotheses, H0: VEi  $\leq$  0.1 versus H1: VEi > 0.1, where VEi is the vaccine efficacy [1 - Pi / Pc] of treatment i, and 0.1 is the vaccine efficacy superiority limit). The superiority-by-a-margin hypotheses will be evaluated using 3 one-sided, two-sample, Bonferroni-adjusted Gart & Nam Likelihood Score tests of the ratio, with an overall (experiment-wise) Type I error rate ( $\alpha$ ) of 0.025. In this study, lower event probabilities are considered to be better. The control group event probability is assumed to be 0.5. To detect the treatment event probabilities 0.35, 0.35, and 0.36 with at least 80% power for each test, the control group sample size needed will be 800 and the number of needed subjects for the treatment groups will be 462, 462, and 462 (totaling 2186 subjects overall).

#### **Dropout-Inflated Sample Size**

| Group | Dropout Rate | Sample Size<br>Ni | Dropout-<br>Inflated<br>Enrollment<br>Sample Size<br>Ni' | Expected<br>Number of<br>Dropouts<br>Di |
|-------|--------------|-------------------|--|---|
| 1     | 20%          | 800               | 1000   | 200                                     |

| 4     | 20%          | 1512              | 1890   | 378                                     |
| Total |              | 7155              | 8944   | 1789                                    |

| Group        | Lists the group numbers.   |
|--------------|--|
| Dropout Rate | The percentage of subjects (or items) that are expected to be lost at random during the course of the study and for whom no response data will be collected (i.e., will be treated as "missing"). Abbreviated as DR.   |
| Ni           | The evaluable sample size for each group at which power is computed (as entered by the user). If Ni subjects are evaluated out of the Ni' subjects that are enrolled in the study, the design will achieve the stated power.   |
| Ni'          | The number of subjects that should be enrolled in each group in order to obtain Ni evaluable subjects, based on the assumed dropout rate. Ni' is calculated by inflating Ni using the formula Ni' = Ni / (1 - DR), with Ni' always rounded up. (See Julious, S.A. (2010) pages 52-53, or Chow, S.C., Shao, J., Wang, H., and Lokhnygina, Y. (2018) pages 32-33.) |
| Di           | The expected number of dropouts in each group. Di = Ni' - Ni.  |

#### **Dropout Summary Statements**

Anticipating a 20% dropout rate, group sizes of 1000, 578, 578, and 578 subjects should be enrolled to obtain final group sample sizes of 800, 462, 462, and 462 subjects.

This report shows the numeric results of this sample size study. Notice that the results are shown in blocks of five rows at a time. Each block represents a single design.

#### **Plots Section**

This plot gives a visual presentation to the results in the Numeric Report. We can quickly see the impact on the sample size of changing the event probability of the first treatment.

# Example 2 – Validation using a Previously Validated Procedure

We could not find a validation result in the statistical literature, so we will use a previously validated PASS procedure (**Superiority by a Margin Tests for Vaccine Efficacy using the Ratio of Two Proportions**) to produce the results for the following example.

A parallel-group, clinical trial is being designed to test the superiority of three dose levels of a test compound against the standard therapy using three superiority by a margin Gart and Nam Likelihood Scores tests. Suppose the standard therapy has an event probability of 0.45. The investigators would like a sample size large enough to detect statistical significance at an overall 0.025 level and an individual-test power of 0.80 when the event rates of all three treatment groups are set to 0.38 because this is the rate that they want to be able to detect. The superiority ratio is 0.5. Note that since there are three tests, the significance level will be set to 0.00833.

In this example, the group sample sizes will be kept equal.

The **Superiority by a Margin Tests for Vaccine Efficacy using the Ratio of Two Proportions** procedure is set up as follows

| Solve For                             | Sample Size                          |
|---------------------------------------|--------------------------------------|
| Power Calculation Method              | Normal Approximation                 |
| Test Type                             | Likelihood Score (Gart & Nam)        |
| Power                                 | 0.8                                  |
| Alpha                                 | <b>0.008333</b> (which is Alpha / k) |
| Group Allocation                      | Equal (N1 = N2)                      |
| Vaccine Efficacy Input Type           | Enter P1.0, P1.1, and P2             |
| P1.0 (Superiority Vaccine Event Prob) | 0.45                                 |
| P1.1 (Actual Vaccine Event Prob)      | 0.35                                 |
| P2 (Control Group Event Probability)  | 0.5                                  |

This set of options generates the following report.

| Solve Fo<br>Test Stat<br>Groups:<br>Hypothes | istic: Gart &<br>1 = Va | Nam Lik<br>ccine, 2 | elihood S<br>= Control<br>vs. H1: |         | 0                |                   |             |        |     |         |
|--|-------------------------|---------------------|-----------------------------------|---------|------------------|-------------------|-------------|--------|-----|---------|
|  |                         |                     |                                   |         |                  | event Probability | <u>'</u>    |        |     |         |
| D  |                         |                     | Vaccine                           |         | Vaccine Efficacy |                   |             |        |     |         |
| Power  |                         | Sample Size         |                                   | Control | Superiority      | Actual            | Superiority | Actual |     |         |
| Target                                       | Actual*                 | N1                  | N2                                | N       | P2               | P1.0              | P1.1        | VE0    | VE1 | Alpha   |
|  |                         | 459                 | 459                               | 918     | 0.5              | 0.45              | 0.35        | 0.1    | 0.3 | 0.00833 |

In order to maintain a power of 80% for all groups, it is apparent that the groups will all need to have a sample size of 459.

Multi-Arm Superiority by a Margin Tests for Vaccine Efficacy using the Ratio of Treatment and Control Proportions

#### Setup

If the procedure window is not already open, use the PASS Home window to open it. The parameters for this example are listed below and are stored in the **Example 2** settings file. To load these settings to the procedure window, click **Open Example Settings File** in the Help Center or File menu.

| Solve For                          | Sample Size                   |
|------------------------------------|-------------------------------|
| Test Type                          | Likelihood Score (Gart & Nam) |
| Power of Each Test                 | 0.80                          |
| Overall Alpha                      | 0.025                         |
| Bonferroni Adjustment              | Standard Bonferroni           |
