Chapter 502

Paired Wilcoxon Signed-Rank Tests for Superiority by a Margin

Introduction

This procedure computes power and sample size for superiority by a margin tests in paired-data designs in which the paired *t*-test assumptions are violated and is the *Paired Wilcoxon Signed-Rank Test* is used.

The details of sample size calculation for the paired design are presented in the Paired T-Tests chapter and they will not be duplicated here. This chapter only discusses those changes necessary for superiority by a margin tests. Sample size formulas for superiority tests of a single mean are presented in Chow et al. (2018) page 43.

Paired Designs

Paired data may occur because two measurements are made on the same subject or because measurements are made on two subjects that have been matched according to other variables. Hypothesis tests on paired data can be analyzed by considering the difference between the paired items as the response. The distribution of differences is usually symmetric. In fact, the distribution must be symmetric if the individual distributions of the two items are identical. Hence, the paired *t*-test is appropriate for paired data even when the distributions of the individual items are not normal.

The Statistical Hypotheses

Both non-inferiority and superiority tests are examples of directional (one-sided) tests and their power and sample size could be calculated using the One-Sample T-Tests procedure. However, at the urging of our users, we have developed this procedure which provides the input and output options that are convenient for superiority hypotheses. This section will review the specifics of superiority testing.

Remember that in the usual *t*-test setting with δ defined as the mean paired difference, the null (H_0) and alternative (H_1) hypotheses for one-sided upper-tail tests are defined as

$$H_0: \delta \le \delta_0 \quad \text{versus} \quad H_1: \delta > \delta_0$$

Rejecting H_0 implies that the mean is larger than the value δ_0. This test is called an *upper-tail test* because H_0 is rejected in samples in which the sample mean is larger than δ_0.

The *lower-tail test* is

$$H_0: \delta \ge \delta_0 \quad \text{versus} \quad H_1: \delta < \delta_0$$

Superiority by a margin tests are special cases of the above directional tests. It will be convenient to adopt the following specialize notation for the discussion of these tests.

Parameter	PASS Input/Output	Interpretation
δ	δ	*Population mean paired difference*. This is the mean of paired differences in the population. This parameter will be estimated by the study.
δ_1	$\delta 1$	*Actual paired difference at which power is calculated*. This is the value of the mean paired difference at which power is calculated.
M_S	SM	*Margin of superiority.* This is a tolerance value that defines the magnitude of difference that is required for practical importance. This may be thought of as the largest difference that is considered to be trivial. The sign is determined by the specific design. This value is used to compute the bound, δ_0.

Superiority by a Margin Tests

A *superiority by a margin test* tests that the mean of paired differences is greater than (or less than) zero by more than a small superiority margin. The actual direction of the hypothesis depends on whether higher values of the response are good or bad.

Case 1: High Values Good

In this case, higher values are better. The hypotheses are arranged so that rejecting the null hypothesis implies that the mean paired difference is greater than zero by at least the margin of superiority. The value of δ at which power is calculated must be greater than $|M_S|$. The null and alternative hypotheses with $\delta_0 = |M_S|$ are

$$H_0: \delta \leq |M_S| \qquad \text{versus} \qquad H_1: \delta > |M_S|$$

Case 2: High Values Bad

In this case, lower values are better. The hypotheses are arranged so that rejecting the null hypothesis implies that the mean is less than the reference value by at least the margin of superiority. The value of δ at which power is calculated must be less than $-|M_S|$. The null and alternative hypotheses with $\delta_0 = -|M_S|$ are

$$H_0: \delta \geq -|M_S| \qquad \text{versus} \qquad H_1: \delta < -|M_S|$$

Paired Wilcoxon Signed-Rank Test Statistic

The Wilcoxon signed-rank test is a popular, nonparametric substitute for the *t*-test. It assumes that the data follow a symmetric distribution. The test is computed using the following steps.

1. Subtract the hypothesized mean, δ_0, from each data value. Rank the values according to their absolute values.

2. Compute the sum of the positive ranks *Sp* and the sum of the negative ranks *Sn*. The test statistic, W_R, is the minimum of *Sp* and *Sn*.

3. Compute the mean and standard deviation of W_R using the formulas

$$\mu_{W_R} = \frac{n(n+1)}{4}$$

$$\sigma_{W_R} = \sqrt{\frac{n(n+1)(2n+1)}{24} - \frac{\sum t^3 - \sum t}{48}}$$

where *t* represents the number of times the *i*th value occurs.

4. Compute the *z*-value using

$$z_W = \frac{W_R - \mu_{W_R}}{\sigma_{W_R}}$$

The significance of the test statistic is determined by computing the p-value using the standard normal distribution. If this p-value is less than a specified level (usually 0.05), the null hypothesis is rejected in favor of the alternative hypothesis. Otherwise, no conclusion can be reached.

Population Size

This is the number of subjects in the population. Usually, you assume that samples are drawn from a very large (infinite) population. Occasionally, however, situations arise in which the population of interest is of limited size. In these cases, appropriate adjustments must be made.

When a finite population size is specified, the standard deviation is reduced according to the formula:

$$\sigma'^2 = \left(1 - \frac{n}{N}\right)\sigma^2$$

where *n* is the sample size, *N* is the population size, σ is the original standard deviation, and σ' is the new standard deviation.

The quantity *n/N* is often called the sampling fraction. The quantity $\left(1 - \frac{n}{N}\right)$ is called the *finite population correction factor*.

The Standard Deviation of Paired Differences (σ)

If you have results from a previous (or pilot) study, use the estimate of the standard deviation of paired differences, σ, from the study. Another reasonable (but somewhat rough) estimate of σ may be obtained using the range of paired differences as

$$\sigma = \frac{Range}{4}$$

If you have estimates of the expected standard deviations of the paired variables (σ_1 and σ_2) and the Pearson correlation between the paired variables (ρ), the standard deviation of paired differences (σ) may be calculated using the equation

$$\sigma^2 = \sigma_1^2 + \sigma_2^2 - 2\rho\sigma_1\sigma_2$$

such that

$$\sigma = \sqrt{\sigma_1^2 + \sigma_2^2 - 2\rho\sigma_1\sigma_2}\,.$$

If $\sigma_1 = \sigma_2 = \sigma_x$, then this formula reduces to

$$\sigma^2 = 2\sigma_x^2(1 - \rho)$$

such that

$$\sigma = \sqrt{2\sigma_x^2(1 - \rho)}\,.$$

If you have an estimate of the within-subject population standard deviation (σ_w), then σ may be calculated using the equation

$$\sigma^2 = 2\sigma_w^2$$

such that

$$\sigma = \sqrt{2\sigma_w^2}\,.$$

σ_w is often estimated by the square root of the within mean square error (WMSE) from a repeated measures ANOVA.

Power Calculation for the Paired Wilcoxon Signed-Rank Test

The power calculation for the Wilcoxon signed-rank test is the same as that for the one-sample t-test except that an adjustment is made to the sample size based on an assumed data distribution as described in Al-Sunduqchi and Guenther (1990). The sample size n' used in power calculations is equal to

$$n' = n/W,$$

where W is the Wilcoxon adjustment factor based on the assumed data distribution.

The adjustments are as follows:

Distribution	W
Uniform	1
Double Exponential	$2/3$
Logistic	$9/\pi^2$
Normal	$\pi/3$

The power is calculated as follows for a directional alternative (one-tailed test) in which $\delta_1 > \delta_0$.

1. Find t_α such that $1 - T_{df}(t_\alpha) = \alpha$, where $T_{df}(t_\alpha)$ is the area under a central-t curve to the left of x and $df = n' - 1$.

2. Calculate: $X_1 = \delta_0 + t_\alpha \frac{\sigma}{\sqrt{n'}}$.

3. Calculate the noncentrality parameter: $\lambda = \frac{\delta_1 - \delta_0}{\frac{\sigma}{\sqrt{n'}}}$.

4. Calculate: $t_1 = \frac{X_1 - \delta_1}{\frac{\sigma}{\sqrt{n'}}} + \lambda$.

5. Power $= 1 - T'_{df,\lambda}(t_1)$, where $T'_{df,\lambda}(x)$ is the area to the left of x under a noncentral-t curve with degrees of freedom df and noncentrality parameter λ.

Example 1 – Power Analysis

Suppose that a test is to be conducted to determine if a new cancer treatment improves the mean bone density. The adjusted mean bone density (AMBD) in the population of interest is 0.002300 gm/cm. Clinicians decide that if the treatment increases AMBD by more than 5% (0.000115 gm/cm), it generates a significant health benefit. They also want to consider what would happen if the margin of superiority is set to 2.5% (0.0000575 gm/cm). The standard deviation of paired differences is 0.000300 gm/cm.

The analysis will be a superiority test using the Wilcoxon signed-rank test at the 0.025 significance level. Power is to be calculated assuming that the new treatment has 7.5% improvement on AMBD. Several sample sizes between 20 and 300 will be analyzed. The researchers want to achieve a power of at least 90%. All numbers have been multiplied by 10000 to make the reports and plots easier to read.

Setup

If the procedure window is not already open, use the PASS Home window to open it. The parameters for this example are listed below and are stored in the **Example 1** settings file. To load these settings to the procedure window, click **Open Example Settings File** in the Help Center or File menu.

0.89804	300	1.150	1.725	3	0.025	0.10196

Power   The probability of rejecting a false null hypothesis when the alternative hypothesis is true.
N   The sample size, the number of subjects (or pairs) in the study.
SM   The magnitude of the margin of superiority. Since higher means are better, this value is positive and is the distance
            above the reference value that is required to be considered superior.
δ   The population mean of paired differences.
δ1   The value of the mean of paired differences at which power and sample size are calculated.
σ   The standard deviation of paired differences for the population.
Alpha   The probability of rejecting a true null hypothesis.
Beta   The probability of failing to reject the null hypothesis when the alternative hypothesis is true.

Summary Statements

A paired design (where higher means are considered to be better) will be used to test whether treatment 1 is
superior to treatment 2 by a margin by testing whether the paired difference in distributions (δ) is greater than
0.575 (H0: δ ≤ 0.575 versus H1: δ > 0.575). The comparison will be made using a one-sided, paired-difference
Wilcoxon Signed-Rank test, with a Type I error rate (α) of 0.025. The underlying data distribution of paired
differences is assumed to be Normal. The underlying standard deviation of the paired difference distribution is
assumed to be 3. To detect a paired mean difference of 1.725 with a sample size of 20 pairs, the power is 0.35274.

Dropout-Inflated Sample Size

Dropout Rate	Sample Size N	Dropout-Inflated Enrollment Sample Size N'	Expected Number of Dropouts D
20%	20	25	5
20%	40	50	10
20%	60	75	15
20%	80	100	20
20%	100	125	25
20%	150	188	38
20%	200	250	50
20%	300	375	75

Dropout Rate   The percentage of subjects (or items) that are expected to be lost at random during the course of the study and for whom no response data will be collected (i.e., will be treated as "missing"). Abbreviated as DR.

N   The evaluable sample size at which power is computed (as entered by the user). If N subjects are evaluated out of the N' subjects that are enrolled in the study, the design will achieve the stated power.

N'   The total number of subjects that should be enrolled in the study in order to obtain N evaluable subjects, based on the assumed dropout rate. N' is calculated by inflating N using the formula N' = N / (1 - DR), with N' always rounded up. (See Julious, S.A. (2010) pages 52-53, or Chow, S.C., Shao, J., Wang, H., and Lokhnygina, Y. (2018) pages 32-33.)

D   The expected number of dropouts. D = N' - N.

Dropout Summary Statements

Anticipating a 20% dropout rate, 25 subjects should be enrolled to obtain a final sample size of 20 subjects.

Plots

The above report shows that for SM = 1.15, the sample size necessary to obtain 90% power is just under 300. However, if SM = 0.575, the required sample size is only about 75.

Example 2 – Finding the Sample Size

Continuing with Example 1, the researchers want to know the exact sample size for each value of SM to achieve 90% power.

Setup

If the procedure window is not already open, use the PASS Home window to open it. The parameters for this example are listed below and are stored in the **Example 2** settings file. To load these settings to the procedure window, click **Open Example Settings File** in the Help Center or File menu.

Numeric Results
_____

Solve For: Sample Size
Higher Means Are: Better
Hypotheses: H0: δ ≤ SM   vs.   H1: δ > SM
Data Distribution: Normal
_____

| | | Paired Differences | | | | |
Power	Sample Size N	Superiority Margin SM	Mean δ1	Standard Deviation σ	Alpha	Beta
0.90215	78	0.575	1.725	3	0.025	0.09785
0.90005	302	1.150	1.725	3	0.025	0.09995

This report shows the exact sample size requirement for each value of SM.

Example 3 – Validation

This procedure uses the same mechanics as the *Paired Wilcoxon Signed-Rank Tests for Non-Inferiority* procedure. We refer the user to Example 3 of Chapter 499 for the validation.
