

## Chapter 109

# Tests for Vaccine Efficacy with Extremely Low Incidence

---

### Introduction

This module provides power analysis and sample size calculation for inequality tests of vaccine efficacy (VE) when the disease incidence rate is extremely low. In this case, large sample sizes are required to meet power requirements. The distribution of the number of cases in each group (vaccine and control) can be approximated by a binomial random variable.

VE is a traditional index of the protective efficacy of a vaccine. It is calculated as

$$VE = \frac{P_2 - P_1}{P_2} = 1 - \frac{P_1}{P_2}$$

where  $P_1$  and  $P_2$  are *attack rates* of the disease being studied among those vaccinated with a new vaccine and those receiving a standard treatment or placebo. An attack rate is the probability that a subject without the disease at the beginning of the study is infected by it during the duration of the course of the study. Hence, an analysis of vaccine effectiveness reduces to an analysis of the ratio of two proportions.

Note that because  $P_1 < P_2$ , the value of  $VE < 1$ .

## Technical Details

This routine is based on Chow et al. (2018), pages 459 - 460.

### Comparing Two Proportions with Low Incidence

Suppose you have two populations from which dichotomous (binary) responses will be recorded. The probability (or risk) of obtaining an event of interest (testing positive for a disease) in population 1 (the treatment group) is  $P_1$  and in population 2 (the control group) is  $P_2$ .

For sufficiently large sample sizes, the number of cases in each group is given by  $\lambda_1 = N_1P_1$  and  $\lambda_2 = N_2P_2$ . The number of cases is distributed approximately as Poisson random variables. The number of cases in the vaccine group given the total number of cases is approximately distributed as a binomial random variable with rate  $\theta$ , where

$$\theta = \frac{\lambda_1}{(\lambda_1 + \lambda_2)} = \frac{1 - VE}{1 - VE + R}$$

where  $R = N_2/N_1$  and  $VE = \left(1 - \frac{P_1}{P_2}\right)$ .

Hence, testing a one-sided hypothesis about VE such as

$$H_0: VE \leq VE_0 \text{ vs. } H_1: VE > VE_0$$

is equivalent to testing the following hypothesis about  $\theta$

$$H_0: \theta \geq \theta_0 \text{ vs. } H_1: \theta < \theta_0$$

### Test Statistics

A reasonable test statistic for the testing the above hypotheses is given by

$$T = \frac{\sqrt{x_1 + x_2}(\hat{\theta} - \theta_0)}{\sqrt{\theta_0(1 - \theta_0)}}$$

where

$$\hat{\theta} = x_1/(x_1 + x_2)$$

$$\theta_0 = \frac{1 - VE_0}{1 - VE_0 + R}$$

In large samples,  $T$  is approximately distributed as a standard normal. The null hypothesis is rejected if  $T < z_{1-\alpha}$ .

In this case,  $\theta_0 = \frac{1}{1+R}$ .

The power, assuming an alternative value of  $P_1 < P_2$ , is given by

$$Power = 1 - \Phi\left(\frac{z_{1-\alpha}\sqrt{\theta_0(1 - \theta_0)} - \sqrt{N_1P_1 + N_2P_2}(\theta_0 - \theta)}{\sqrt{\theta(1 - \theta)}}\right)$$

This power formula can be used directly for obtaining power or indirectly for obtaining sample size using a simple, binary search.

Note that the power formula given here uses the difference between the two terms in the numerator while the formula given on page 460 of Chow et al. (2018) uses the sum of these terms. This difference is most likely due to a difference in the definition of  $z_\alpha$  here as the left-tail probability rather than the right-tail probability.

## Example 1 – Finding Sample Size

A two-arm parallel study is being planned to substantiate that a new vaccine controls a certain disease better than a control. The disease rate in the control group is 0.003. The disease rate in the treatment group is anticipated to be between 0.001 and 0.002. The significance level of the test is 0.025.

The sample sizes will be equal in each arm. The current analysis is to determine the required sample size to achieve a power of 0.80.

### Setup

This section presents the values of each of the parameters needed to run this example. First, from the PASS Home window, load the procedure window. You may then make the appropriate entries as listed below, or open **Example 1** by going to the **File** menu and choosing **Open Example Template**.

<u>Option</u>	<u>Value</u>
<b>Design Tab</b>	
Solve For .....	<b>Sample Size</b>
Power.....	<b>0.8</b>
Alpha.....	<b>0.025</b>
Group Allocation .....	<b>Equal (N1 = N2)</b>
Vaccine Efficacy Input Type .....	<b>Enter P1 and P2</b>
P1 (Vaccine Event Prob H1).....	<b>0.001 0.0015 0.002</b>
P2 (Control Event Probability) .....	<b>0.003</b>

### Annotated Output

Click the Calculate button to perform the calculations and generate the following output.

#### Numeric Results

##### Numeric Results

Test Statistic: Z Test

Hypotheses:  $H_0: VE \leq 0$  vs.  $H_1: VE > 0$

Target Power	Actual Power	N1	N2	N	Event Probability		Vaccine Efficacy VE	Alpha
					Vax P1	Cntl P2		
0.8	0.80001	7230	7230	14460	0.0010	0.003	0.66667	0.025
0.8	0.80000	15163	15163	30326	0.0015	0.003	0.50000	0.025
0.8	0.80001	38770	38770	77540	0.0020	0.003	0.33333	0.025

## Tests for Vaccine Efficacy with Extremely Low Incidence

### Report Definitions

Target Power is the desired power value. Power is the probability of rejecting a false null hypothesis.  
 Actual Power is the calculated power obtained for the scenario on this row. Because N1 and N2 are discrete, this value is often (slightly) larger than the target power.  
 N1 and N2 are the sample sizes of the vaccinated group and the control group, respectively.  
 N is the total sample size, N1 + N2.  
 P1 is the event probability of the vaccinated group assumed by H1.  
 P2 is the event probability (attack rate) of the control group.  
 VE is the vaccine efficacy assumed by the alternative hypothesis, H1. This is the VE value at which the power is calculated.  $VE = (P2 - P1)/P2$ .  
 Alpha is the probability of rejecting a true null hypothesis.

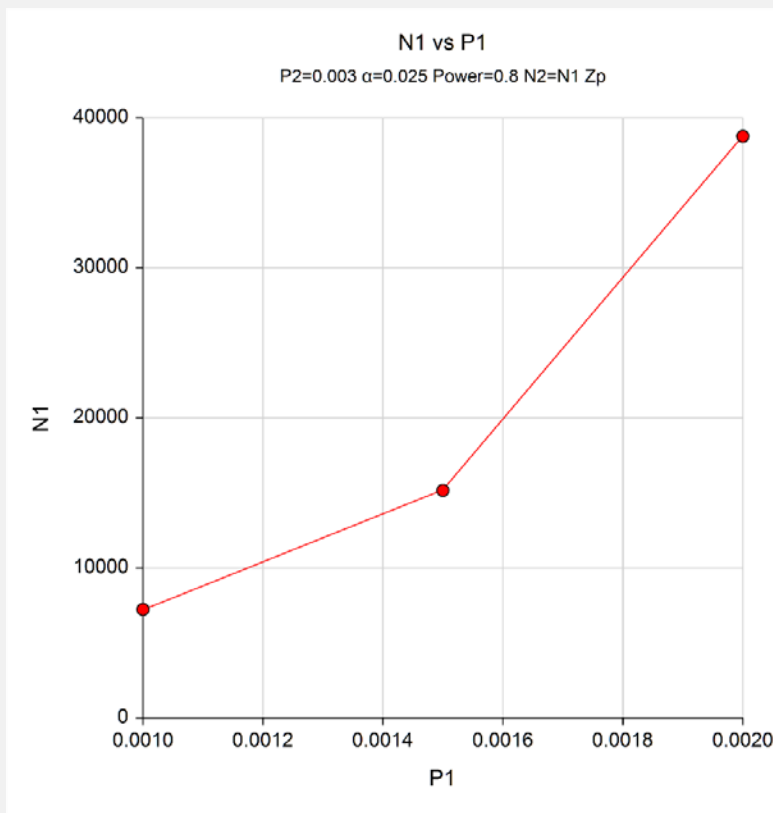

### Summary Statements

Sample sizes of 7230 in the vaccine group and 7230 in the control group achieve 80% power to detect a vaccine efficacy of 0.66667. The significance level of the test is 0.025. The control group event probability is 0.003. The power was computed for the case when the actual vaccine group event probability is 0.001. The test statistic used is the one-sided Z Test.

This report shows the values of each of the parameters, one scenario per row.

## Chart Section

### Chart Section

The values from the table are displayed in the above chart. This chart gives a quick look at the sample sizes that are required for various values of P1.

## Example 2 – Validation using Chow et al. (2018)

Chow et al. (2018) page 460 presents an example which will be used to validate this procedure. In this example, a two-arm parallel study is being planned to substantiate that a new vaccine controls a certain disease better than a control. The disease rate in the control group is 0.002. The disease rate in the treatment group is anticipated to be 0.001. The significance level of the test is 0.05 and the power is 0.80. The anticipated sample size is 17837 per group.

### Setup

This section presents the values of each of the parameters needed to run this example. First, from the PASS Home window, load the procedure window. You may then make the appropriate entries as listed below, or open **Example 2** by going to the **File** menu and choosing **Open Example Template**.

<u>Option</u>	<u>Value</u>
<b>Design Tab</b>	
Solve For .....	<b>Sample Size</b>
Power.....	<b>0.8</b>
Alpha.....	<b>0.05</b>
Group Allocation .....	<b>Equal (N1 = N2)</b>
Vaccine Efficacy Input Type .....	<b>Enter P1 and P2</b>
P1 (Vaccine Event Prob H1).....	<b>0.001</b>
P2 (Control Event Probability) .....	<b>0.002</b>

### Annotated Output

Click the Calculate button to perform the calculations and generate the following output.

#### Numeric Results

Numeric Results									
Test Statistic: Z Test									
Hypotheses: H0: VE ≤ 0 vs. H1: VE > 0									
Target Power	Actual Power	N1	N2	N	Event Probability		Vaccine Efficacy VE	Alpha	
					Vax P1	Cntl P2			
0.8	0.80001	17837	17837	35674	0.001	0.002	0.5	0.05	

PASS has also calculated the sample size to be 17,837 per group. Thus, the procedure is validated.
