Chapter 170

Tests for the Odds Ratio of Two Proportions in a 2x2 Cross-Over Design

Introduction

Senn (2002) defines a *cross-over* design as one in which each subject receives all treatments, and the objective is to study differences among the treatments. The name *cross-over* comes from the most common case in which there are only two treatments. In this case, each subject *crosses over* from one treatment to the other. It is assumed that there is a *washout* period between treatments during which the response returns back to its baseline value. If this does not occur, there is said to be a *carry-over* effect.

A 2×2 cross-over design contains two *sequences* (treatment orderings) and two time periods (occasions). One sequence receives treatment A followed by treatment B. The other sequence receives B and then A. The design includes a washout period between responses to make certain that the effects of the first drug do not carry over to the second. Thus, the groups in this design are defined by the sequence in which the drugs are administered, not by the treatments they receive. Indeed, higher-order cross-over designs have been used in which the same treatment is used on both occasions.

Cross-over designs are employed because, if the no-carryover assumption is met, treatment differences are measured within a subject rather than between subjects—making a more precise measurement. Examples of the situations that might use a cross-over design are the comparison of anti-inflammatory drugs in arthritis and the comparison of hypotensive agents in essential hypertension. In both cases, symptoms are expected to return to their usual baseline level shortly after the treatment is stopped.

The sample size calculations in the procedure are based on the formulas presented in Lui (2016).

Advantages of Cross-Over Designs

A comparison of treatments on the same subject is expected to be more precise. The increased precision often translates into a smaller sample size. Also, patient enrollment into the study may be easier because each patient will receive both treatments. Finally, it is often more difficult to obtain a subject than to obtain a measurement.

Disadvantages of Cross-Over Designs

The statistical analysis of a cross-over experiment is more complex than a parallel-group experiment and requires additional assumptions. It may be difficult to separate the treatment effect from the period effect, the carry-over effect of the previous treatment, and the interaction between period and treatment.

The design cannot be used when the treatment (or the measurement of the response) alters the subject permanently. Hence, it should not be used to compare treatments that are intended to provide a cure.

Because subjects must be measured at least twice, it is often more difficult to keep patients enrolled in the study. It is arguably simpler to measure a subject once than to obtain their measurement twice. This is particularly true when the measurement process is painful, uncomfortable, embarrassing, or time consuming.

Technical Details

The 2×2 crossover design may be described as follows. Randomly assign the subjects to one of two sequence groups so that there are n_1 subjects in sequence one and n_2 subjects in sequence two. In order to achieve design balance, the sample sizes n_1 and n_2 are assumed to be equal so that $n_1 = n_2 = n = N/2$.

Sequence one is given the control (A) followed by the treatment (B). Sequence two is given the treatment (B) followed by the control (A).

The design can be analyzed using a simple *z*-test if we ignore period and sequence effects or using a more complex random effects logistic regression model that adjusts for period and sequence effects. The sample size calculations herein ignore period and sequence effects. Julious (2010) suggests on page 175 that the bias due to ignoring period effects if a period-adjusted analysis is planned is not great and that sample size calculations that ignore period effects are adequate.

Cross-Over Design

The discussions that follow summarize the results in Lui (2016). Consider a 2×2 cross-over design and let $x_{ij}^{(g)}$ represent the binary response (0 or 1) from the *j*th subject, *j* = 1, ..., n_g, in the *i*th period (*i* = 1, 2), in sequence *g* (*g* = 1, 2). Let $n_{rc}^{(g)}$ represent the number of subjects among n_g subjects in sequence *g* with the response vector ($x_{1j} = r$, $x_{2j} = c$). We can then summarize the results in terms of counts from a cross-over design with the following table for sequences 1 and 2 as

SEQUENCE 1 (Control → Treatment)

		Period 2 (Treatment)		
		Yes	No	Total
Period 1 (Control)	Yes	$n_{11}^{(1)}$	$n_{10}^{(1)}$	$n_{1\cdot}^{(1)}$
	No	$n_{01}^{(1)}$	$n_{00}^{(1)}$	$n_{0\cdot}^{(1)}$
	Total	$n_{\cdot1}^{(1)}$	$n_{\cdot0}^{(1)}$	n_1

SEQUENCE 2 (Treatment → Control)

		Period 2 (Control)		
		Yes	No	Total
Period 1 (Treatment)	Yes	$n_{11}^{(2)}$	$n_{10}^{(2)}$	$n_{1\cdot}^{(2)}$
	No	$n_{01}^{(2)}$	$n_{00}^{(2)}$	$n_{0\cdot}^{(2)}$
	Total	$n_{\cdot1}^{(2)}$	$n_{\cdot0}^{(2)}$	n_2

In terms of proportions, the 2×2 cross-over design tables can be summarized as

SEQUENCE 1 (Control → Treatment)

		Period 2 (Treatment)		
		Yes	No	Total
Period 1 (Control)	Yes	$P_{11}^{(1)}$	$P_{10}^{(1)}$	$P_{1\cdot}^{(1)}$
	No	$P_{01}^{(1)}$	$P_{00}^{(1)}$	$P_{0\cdot}^{(1)}$
	Total	$P_{\cdot 1}^{(1)}$	$P_{\cdot 0}^{(1)}$	1

SEQUENCE 2 (Treatment → Control)

		Period 2 (Control)		
		Yes	No	Total
Period 1 (Treatment)	Yes	$P_{11}^{(2)}$	$P_{10}^{(2)}$	$P_{1\cdot}^{(2)}$
	No	$P_{01}^{(2)}$	$P_{00}^{(2)}$	$P_{0\cdot}^{(2)}$
	Total	$P_{\cdot 1}^{(2)}$	$P_{\cdot 0}^{(2)}$	1

with the individual proportions estimated as

$$\hat{P}_{rc}^{(g)} = \frac{n_{rc}^{(g)}}{n_g}.$$

Lui (2016) indicates on pages 32-42 that the odds ratio for the treatment versus the control (O_T/O_C) is defined for a 2×2 cross-over design as

$$OR = \sqrt{\frac{P_{01}^{(1)} P_{10}^{(2)}}{P_{10}^{(1)} P_{01}^{(2)}}}$$

with estimate

$$\widehat{OR} = \sqrt{\frac{\hat{P}_{01}^{(1)} \hat{P}_{10}^{(2)}}{\hat{P}_{10}^{(1)} \hat{P}_{01}^{(2)}}}.$$

The estimated log odds ratio, $\log(\widehat{OR})$, has asymptotic variance σ^2/n with

$$\sigma^2 = \frac{1}{4}\left(\frac{1}{P_{01}^{(1)}} + \frac{1}{P_{10}^{(1)}} + \frac{1}{P_{01}^{(2)}} + \frac{1}{P_{10}^{(2)}}\right)$$

which can be estimated as

$$\hat{\sigma}^2 = \frac{1}{4}\left(\frac{1}{\hat{P}_{01}^{(1)}} + \frac{1}{\hat{P}_{10}^{(1)}} + \frac{1}{\hat{P}_{01}^{(2)}} + \frac{1}{\hat{P}_{10}^{(2)}}\right).$$

The standard deviation, then, is

$$SD = \sigma = \sqrt{\sigma^2}$$

with estimate

$$\widehat{SD} = \hat{\sigma} = \sqrt{\hat{\sigma}^2}.$$

Test Statistic

For a two-sided test of the hypotheses

$$H_0: OR = 1 \quad \text{vs.} \quad H_A: OR \neq 1$$

the power and sample size calculations are based on the test statistic

$$Z = \frac{\log(\widehat{OR})}{\frac{\widehat{SD}}{\sqrt{n}}}$$

which is asymptotically distributed as standard normal under the null hypothesis. The null hypothesis is rejected in favor of the alternative at level α if

$$\frac{\left|\log(\widehat{OR})\right|}{\frac{\widehat{SD}}{\sqrt{n}}} > Z_{1-\alpha/2}$$

where $Z_{1-\alpha/2}$ is the upper $1 - \alpha/2$ percentile of the standard normal distribution. One-sided tests reject the null hypothesis at level α if

$$\frac{\left|\log(\widehat{OR})\right|}{\frac{\widehat{SD}}{\sqrt{n}}} > Z_{1-\alpha}$$

where $Z_{1-\alpha}$ is the upper $1 - \alpha$ percentile of the standard normal distribution.

Power Calculation

Derived from the sample size formula given in Lui (2016) on page 42, the power for the two-sided test of $H_0: OR = 1$ versus $H_A: OR \neq 1$ is

$$\Phi\left(\frac{|\log(OR_1)|}{\frac{SD}{\sqrt{n}}} - Z_{1-\alpha/2}\right)$$

where $\Phi()$ is the standard normal distribution function, OR_1 is a value of the odds ratio under the alternative hypothesis, and $Z_{1-\alpha/2}$ is the upper $1 - \alpha/2$ percentile of the standard normal distribution. The sample size calculation formula for a two-sided test is

$$n = \text{Ceiling}\left\{\left(\frac{(Z_{1-\alpha/2} + Z_{1-\beta})SD}{\log(OR_1)}\right)^2\right\}.$$

The power for a one-sided test is

$$\Phi\left(\frac{|\log(OR_1)|}{\frac{SD}{\sqrt{n}}} - Z_{1-\alpha}\right)$$

where $Z_{1-\alpha}$ is the upper $1 - \alpha$ percentile of the standard normal distribution. The sample size calculation formula for a one-sided test is

$$n = \text{Ceiling}\left\{\left(\frac{(Z_{1-\alpha} + Z_{1-\beta})SD}{\log(OR_1)}\right)^2\right\}.$$

Example 1 – Power Analysis

Suppose you want to consider the power of a balanced cross-over design with a binary endpoint where the test is computed based on the odds ratio for sequence sample sizes between 50 and 200. The odds ratio to detect is 2 and the estimated standard deviation of the log odds ratio is 2.5. The significance level is 0.05.

Setup

If the procedure window is not already open, use the PASS Home window to open it. The parameters for this example are listed below and are stored in the **Example 1** settings file. To load these settings to the procedure window, click **Open Example Settings File** in the Help Center or File menu.

Numeric Results
───
Solve For: Power
Alternative Hypothesis: Two-Sided
Hypotheses: H0: OR = 1   vs.   H1: OR ≠ 1
───

| | Sample Size | | Odds Ratio | Standard Deviation | |
Power	Sequence n	Total N	OR1	SD	Alpha
0.50022	50	100	2	2.5	0.05
0.67045	75	150	2	2.5	0.05
0.79178	100	200	2	2.5	0.05
0.87283	125	250	2	2.5	0.05
0.92446	150	300	2	2.5	0.05
0.95617	175	350	2	2.5	0.05
0.97506	200	400	2	2.5	0.05

Power   The probability of rejecting a false null hypothesis when the alternative hypothesis is true.
n   The sample size in each sequence (or group).
N   The total combined sample size from both sequences.
OR1   The odds ratio under the alternative hypothesis.
SD   The user-entered standard deviation. This is estimated from a previous study.
Alpha   The probability of rejecting a true null hypothesis.

Summary Statements

A 2×2 cross-over design will be used to test whether the treatment proportion is different from the standard proportion by comparing the odds ratio (OR = Ot / Oc) to 1 (H0: OR = 1 versus H1: OR ≠ 1). The comparison will be made using a two-sided log odds ratio Z-test, with a Type I error rate (α) of 0.05. The standard deviation of the log odds ratio is assumed to be 2.5. To detect an odds ratio of 2 with a sample size of 50 in each sequence (totaling 100 subjects), the power is 0.50022.

Dropout-Inflated Sample Size

	Sample Size		Dropout-Inflated Enrollment Sample Size		Expected Number of Dropouts	
Dropout Rate	n	N	n'	N'	d	D
20%	50	100	63	126	13	26
20%	75	150	94	188	19	38
20%	100	200	125	250	25	50
20%	125	250	157	314	32	64
20%	150	300	188	376	38	76
20%	175	350	219	438	44	88
20%	200	400	250	500	50	100

Dropout Rate   The percentage of subjects (or items) that are expected to be lost at random during the course of the study and for whom no response data will be collected (i.e., will be treated as "missing"). Abbreviated as DR.

n and N   The evaluable group and total sample sizes, respectively, at which power is computed (as entered by the user). If n subjects from each group are evaluated out of the n' subjects that are enrolled in the study, the design will achieve the stated power. N = 2n.

n' and N'   The number of subjects that should be enrolled in the study in order to obtain n and N evaluable subjects, based on the assumed dropout rate. n' is calculated by inflating n using the formula n' = n / (1 - DR), with n' always rounded up. (See Julious, S.A. (2010) pages 52-53, or Chow, S.C., Shao, J., Wang, H., and Lokhnygina, Y. (2018) pages 32-33.). N' = 2n'.

d and D   The expected number of group and total dropouts, respectively. d = n' - n and D = 2d.
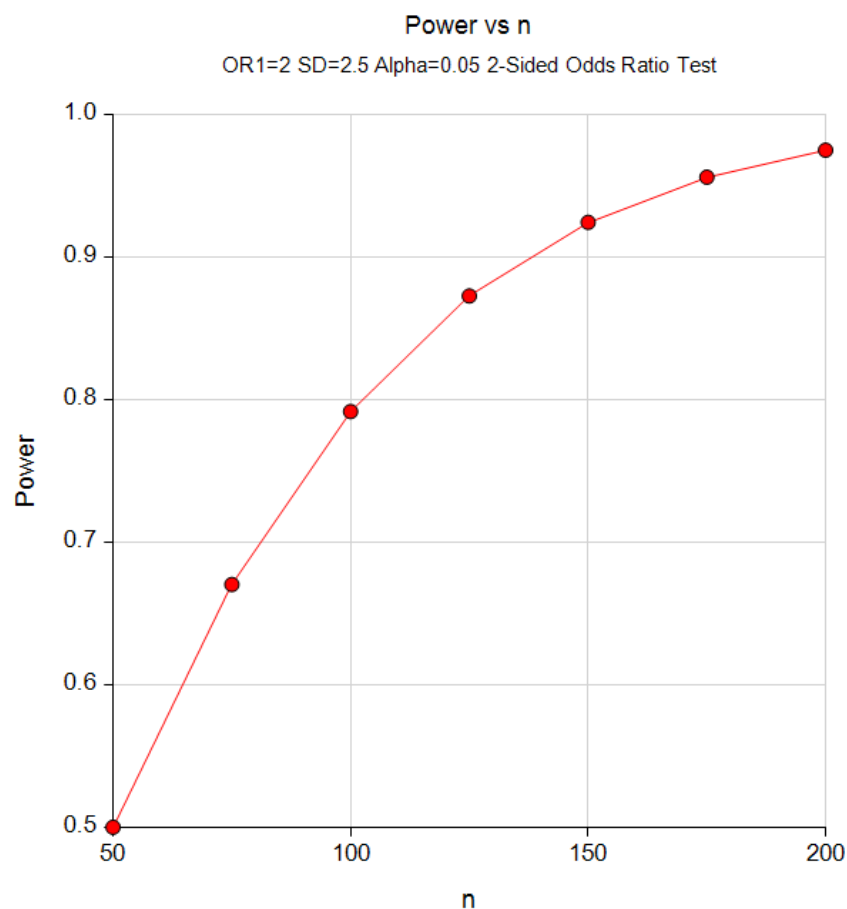

Dropout Summary Statements

Anticipating a 20% dropout rate, 63 subjects should be enrolled in each group to obtain final sample sizes of 50 subjects per group.

Plots

This report shows the values of each of the parameters, one scenario per row. This plot shows the relationship between sample size and power. We see that a sample size of just over 100 per sequence is required to detect an odds ratio of 2 with 80% power.

Example 2 – Calculating Sample Size when Estimating the Standard Deviation from a Previous Study (Validation using Hand Calculations)

This example demonstrates how to calculate the sample size when estimating the standard deviation of the log odds ratio from data in a previous study using the method in Lui (2016) on page 42. In this example we'll find the sample size required to detect an odds ratio of 2 with 80% power at a significance level of 0.05, with the standard deviation estimated from discordant proportions from a previous study.

Table 3.2 of Lui (2016) on page 36 presents the following results from 279 subjects a simple 2x2 cross-over trial comparing two inhalation devices, A and B.

SEQUENCE 1 (Control (A) → Treatment (B))

		Period 2 (B)		
		Yes	No	Total
Period 1 (A)	Yes	26	41	67
	No	15	57	72
	Total	41	98	139

SEQUENCE 2 (Treatment (B) → Control (A))

		Period 2 (A)		
		Yes	No	Total
Period 1 (B)	Yes	38	16	54
	No	32	54	86
	Total	70	70	140

The discordant proportions are estimated as

$$\hat{P}_{01}^{(1)} = \frac{15}{139} = 0.1079$$

$$\hat{P}_{10}^{(1)} = \frac{41}{139} = 0.2950$$

$$\hat{P}_{01}^{(2)} = \frac{32}{140} = 0.2286$$

$$\hat{P}_{10}^{(2)} = \frac{16}{140} = 0.1143$$

Using the method of Lui (2016) on page 42, SD is estimated as

$$\widehat{SD} = \sqrt{\hat{\sigma}^2}$$

$$= \sqrt{\frac{1}{4}\left(\frac{1}{\hat{P}_{01}^{(1)}} + \frac{1}{\hat{P}_{10}^{(1)}} + \frac{1}{\hat{P}_{01}^{(2)}} + \frac{1}{\hat{P}_{10}^{(2)}}\right)}$$

$$= \sqrt{\frac{1}{4}\left(\frac{1}{0.1079} + \frac{1}{0.2950} + \frac{1}{0.2286} + \frac{1}{0.1143}\right)}$$

$$= \mathbf{2.5388}$$

PASS will calculate this SD value for you automatically when you input the discordant cell proportions.

Since there is no example given for this calculation in the book, we'll validate this procedure using hand calculations. The sample size calculated by hand using the equation on Lui (2016) page 42 is

$$n = \text{Ceiling}\left\{\left(\frac{(Z_{1-\alpha/2} + Z_{1-\beta})SD}{\log(OR_1)}\right)^2\right\} = \text{Ceiling}\left\{\left(\frac{(1.96 + 0.84)2.5388}{\log(2)}\right)^2\right\}$$

$$= \text{Ceiling}\{105.177\}$$

$$= 106$$

Setup

If the procedure window is not already open, use the PASS Home window to open it. The parameters for this example are listed below and are stored in the **Example 2** settings file. To load these settings to the procedure window, click **Open Example Settings File** in the Help Center or File menu.
